Executive Summary

This report provides a complete data preprocessing on the unemployment rates between males and females in different countries around the world. There are several stages which I do in this data preprocessing. Firstly, I imported both data into r studio using readr package separately. Secondly, I tidy up the data using pivot_longer (). After tidying up the data, I merge these two data using the inner_join () function. Thirdly, I do a check on the data types using the str (), class (), attributes () function and then convert the data types to the proper type. Moreover, I also do labeling on one of the factor variables. Fourthly, I create/mutate a new variable from the combination of data I have. Fifthly, I scan for missing values, special values, obvious errors, and outliers then applying a proper methodology to deal with them. Lastly, I did the data transformation to reduce skewness and make the data normally distributed.

Data

- Data description: The datasets that I used represent the unemployment rates between males and females in different countries around the world. The first dataset and second dataset represents the males unemployment rate and females unemployment rate respectively.
- Both of the data was taken from The World Bank website. Male unemployment rate: https://databank.worldbank.org/reports.aspx?source=2&series=SL.UEM.TOTL.MA.ZS&country= (https://databank.worldbank.org/reports.aspx?source=2&series=SL.UEM.TOTL.MA.ZS&country=) Female unemployment rate: https://databank.worldbank.org/reports.aspx?source=2&series=SL.UEM.TOTL.FE.ZS&country= (https://databank.worldbank.org/reports.aspx?source=2&series=SL.UEM.TOTL.FE.ZS&country=)
- Variable description: Both of these datasets have the same variables, the only difference is that the first data represents males and the second data represents females.
    - Country name: name of the country
    - Country code: unique code of the country
    - Year 2011-2019: represent unemployment rate of different year

```
#Import male unemployment rate using readr package.
male_unemployment_rate <- read_csv("C:/Users/andre/OneDrive/Desktop/Data Wrangling/Practical
 Assessment 2/Practical Assessment 2/Male unemployment rate.csv")
```

```

6 rows | 1-7 of 11 columns

Step explaination:

- Firstly, I import both of the data using readr function.
- Secondly, I used head() function to display the first 6 observations.
- Before merging the data, I will tidy up both of the male_unemployment_rate and female_unemployment_rate dataset above and give them the names tidy_male_unemployment_rate and tidy_female_unemployment_rate. Further explanation can be found on the Tidy & Manipulate Data I section below.

Tidy & Manipulate Data I

- There are three interrelated rules which make a dataset tidy by Wickham and Grolemund (2016). In tidy data: -Each variable must have its own column. -Each observation must have its own row. -Each value must have its own cell.
- The data above is not tidy because the years 2011 - 2019 are separated in 9 variables, instead they should be combined into one variable named “Year”. Therefore, I used pivot_longer () function below to combine them into a single variable named “Year”.

```
#Combine 2011 - 2019 variables into one variable named "Year" for male dataset. Then, assign
 it to variable tidy_male_unemployment_rate.
tidy_male_unemployment_rate <- male_unemployment_rate %>% pivot_longer(cols = -c("Country Nam
e", "Country Code"), names_to = "Year", values_to = "Unemployment rate") %>% rename(`Male une
mployment rate` = `Unemployment rate`)

#Combine 2011 - 2019 variables into one variable named "Year" for female dataset. Then, assig
n it to variable tidy_female_unemployment_rate.
tidy_female_unemployment_rate <- female_unemployment_rate %>% pivot_longer(cols = -c("Country
Name", "Country Code"), names_to = "Year", values_to = "Unemployment rate") %>% rename(`Femal
e unemployment rate` = `Unemployment rate`)
```

```
#Display the first several rows of tidy_male_unemployment_rate using head() function.
head(tidy_male_unemployment_rate)
```

Country Name <chr>	Country Code <chr>	Year <chr>	Male unemployment rate <chr>
Afghanistan	AFG	2011 [YR2011]	10.89999962
Afghanistan	AFG	2012 [YR2012]	10.88000011
Afghanistan	AFG	2013 [YR2013]	10.89000034
Afghanistan	AFG	2014 [YR2014]	10.77999973
Afghanistan	AFG	2015 [YR2015]	10.68000031
Afghanistan	AFG	2016 [YR2016]	10.56999969

6 rows

```
#Display the first several rows of tidy_females_unemployment_rate using head() function.
head(tidy_female_unemployment_rate)
```

Country Name <chr>	Country Code <chr>	Year <chr>	Female unemployment rate <chr>
Afghanistan	AFG	2011 [YR2011]	14.78999996
Afghanistan	AFG	2012 [YR2012]	14.85999966
Afghanistan	AFG	2013 [YR2013]	14.69999981
Afghanistan	AFG	2014 [YR2014]	14.52999973
Afghanistan	AFG	2015 [YR2015]	14.44999981
Afghanistan	AFG	2016 [YR2016]	14.32999992

6 rows

Step explaination:

- I combined 2011 - 2019 variables into one variable named Year.
- Then, I recheck the data using head(). The 2011 - 2019 variable has been combined into one variable named Year.

Data

```
#Merged the tidy_male_unemployment_rate with tidy_female_unemployment_rate. Then, named it me
rged_malefemale_UR.
merged_malefemale_UR <- tidy_male_unemployment_rate %>% inner_join(tidy_female_unemployment_r
ate, by = c("Country Code", "Year", "Country Name"))

#Display the first several rows of merged_malefemale_UR.
head(merged_malefemale_UR)
```

Country Name <chr>	Country Code <chr>	Year <chr>	Male unemployment rate <chr>	Female unemployme <chr>
Afghanistan	AFG	2011 [YR2011]	10.89999962	14.78999996
Afghanistan	AFG	2012 [YR2012]	10.88000011	14.85999966
Afghanistan	AFG	2013 [YR2013]	10.89000034	14.69999981
Afghanistan	AFG	2014 [YR2014]	10.77999973	14.52999973
Afghanistan	AFG	2015 [YR2015]	10.68000031	14.44999981
Afghanistan	AFG	2016 [YR2016]	10.56999969	14.32999992

6 rows

Step explaination:

- Merged data using inner_join function and give it a new name “merged_malefemale_UR”.
- Use head to display the first 6 observations of the merged_malefemale_UR.

Understand

```
#Inspect the data structures before conversion

#rechecking the data structures after conversion.
str(merged_malefemale_UR)
```

```
## tibble [2,376 x 5] (S3: tbl_df/tbl/data.frame)
##  $ Country Name            : chr [1:2376] "Afghanistan" "Afghanistan" "Afghanistan" "Afgha
nistan" ...
##  $ Country Code            : Factor w/ 264 levels "ABW","AFG","AGO",..: 2 2 2 2 2 2 2 2 2
4 ...
##  $ Year                    : Factor w/ 9 levels "2011","2012",..: 1 2 3 4 5 6 7 8 9 1 ...
##  $ Male unemployment rate  : num [1:2376] 10.9 10.9 10.9 10.8 10.7 ...
##  $ Female unemployment rate: num [1:2376] 14.8 14.9 14.7 14.5 14.4 ...
```

Step explaination:

- Firstly, I inspect the data using str(), class(), and attributes() functions.
- Secondly, I converted the data into factors and numberics. I also labelled the Year variable.
- Lastly, I recheck the data structures using str() function. As the result now the data

Tidy & Manipulate Data II

```
#Mutate new variable named Unemployment rate gap between genders.
merged_mutated_MF_UR <- mutate(merged_malefemale_UR, `Unemployment rate gap between genders`
 = `Male unemployment rate` - `Female unemployment rate`)

#Display the new variable and several first observations of the merged_mutated_MF_UR dataset.
head(merged_mutated_MF_UR)
```

Country Name <chr>	Country Code <fct>	Y… <fct>	Male unemployment rate <dbl>	Female unemployment rate <dbl>
Afghanistan	AFG	2011	10.90	14.79
Afghanistan	AFG	2012	10.88	14.86
Afghanistan	AFG	2013	10.89	14.70
Afghanistan	AFG	2014	10.78	14.53
Afghanistan	AFG	2015	10.68	14.45
Afghanistan	AFG	2016	10.57	14.33

6 rows | 1-5 of 6 columns

Step explaination:

- In this step, I use mutate() function to create a new variable named “Unemployment rate gap between genders” which represent the difference between males unemployement rate and females unemployment rate.
- Then, I used head() function to display the new mutated variable and their first 6 observations.

Scan I

```
#scan for missing values
colSums(is.na(merged_mutated_MF_UR))
```

```

##                         Country Name                         Country Code
##                                    0                                    0
##                                 Year               Male unemployment rate
##                                    0                                    0
##            Female unemployment rate Unemployment rate gap between genders
##                                    0                                    0
```

Step explaination:

- Firstly, I checked the missing values, special values, and obvious errors (inconsistencies).
- Secondly, I checked the complete observations of the data.
- Lastly, I omitted the missing values using na.omit() function and assign it to new variable named scan_MF_UR.

Methodology:

For each country in this dataset, the country have either full/complete data (2011 - 2019) or missing all the data (NA for all years 2011 - 2019). Thus, replacing / imputing missing data with data from other countries would not be appropriate because it will bias the distribution of the dataset I am using. Therefore, I chose to omit the missing data (279 observations omitted) and ended up with 2097 complete observations of year 2011 - 2019 for every country.

Step explaination:

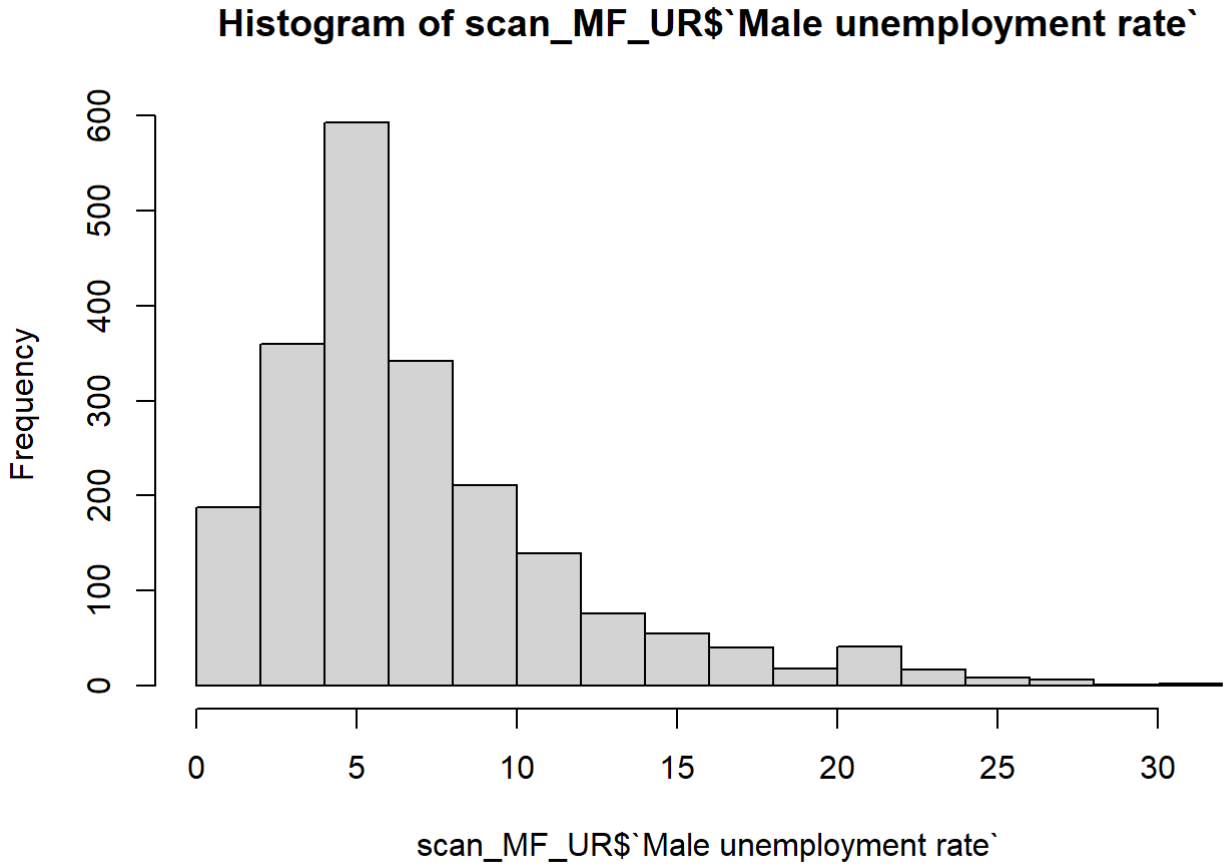
- Firstly, I check the univariate outliers using the boxplot().
- Secondly, I check the multivariate outliers using boxplot, scatterplot, and mahalanobis distance.

Methodology:

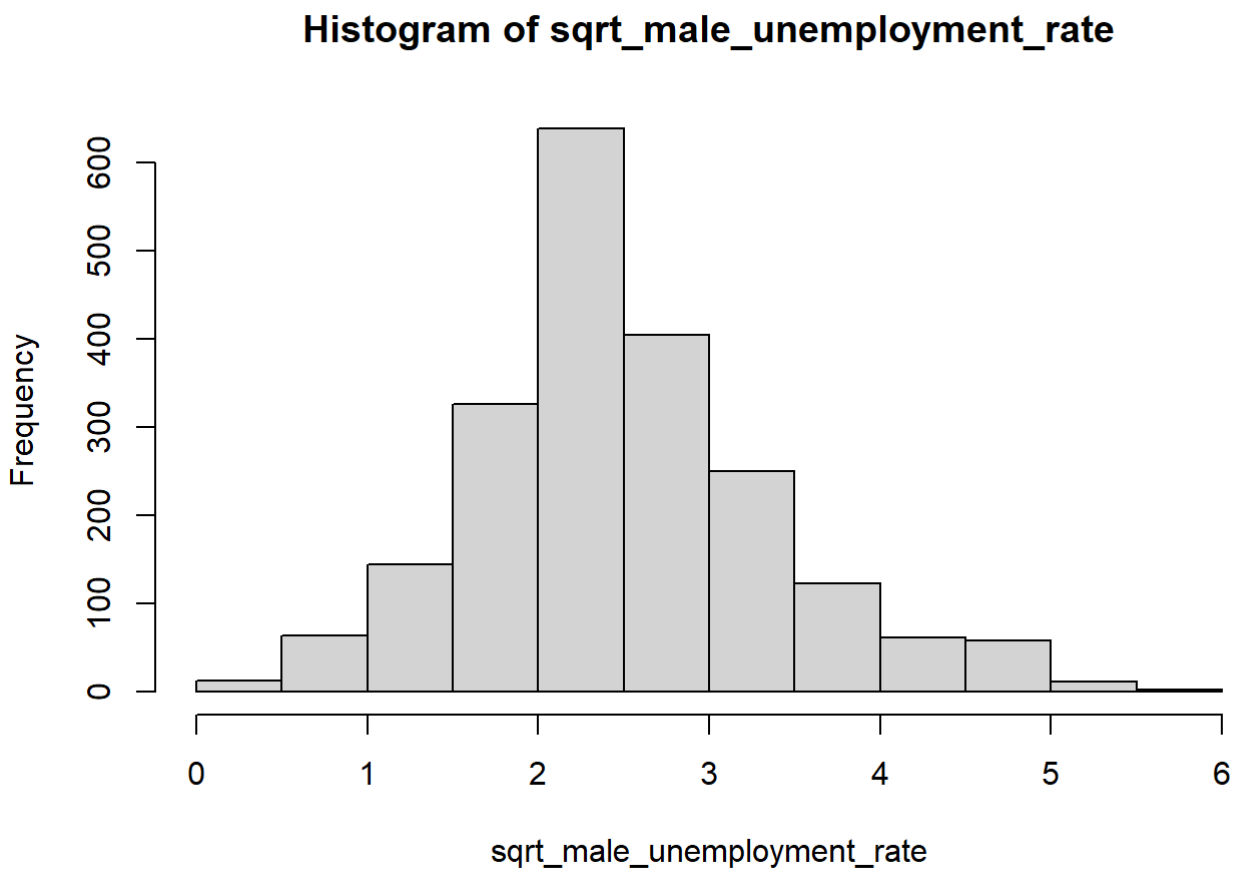
Although the univariate boxplot and QQ plots illustrates that the data I use have many outliers. However, the multivariate boxplot and scatter plot show that the unemployment rates from one country to another can vary widely. For example, Australia has an unemployment rate of 5% compared to a country that is still in civil war like Libya, which has an unemployment rate as high as 25%. As it is known that the real world is filled with outliers, so to model the real world I believe that keeping the outliers will be beneficial for my analysis in this particular datasets.

Transform

```
#Male unemployment rate before transformation
hist(scan_MF_UR$`Male unemployment rate`)
```

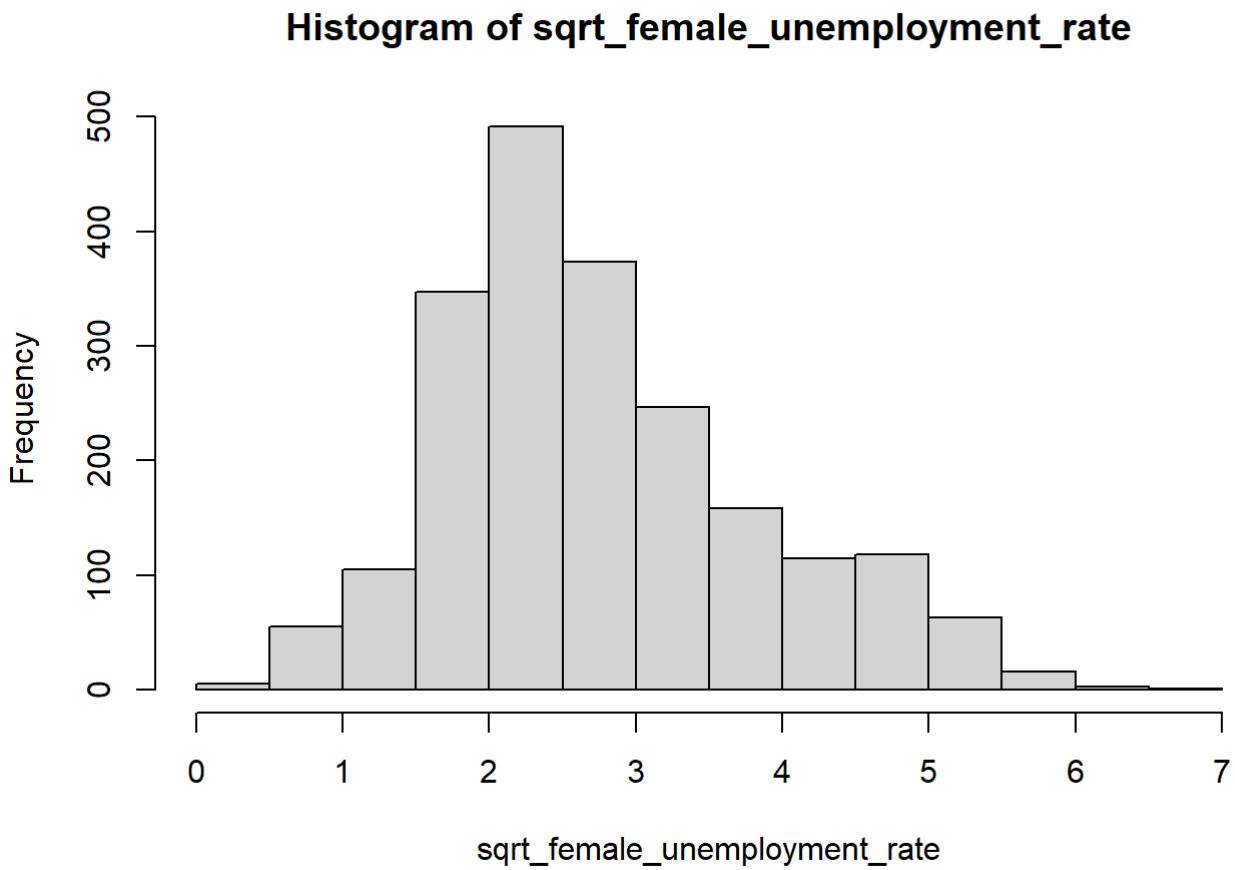


```
#Male unemployment rate after transformation
sqrt_male_unemployment_rate <- sqrt(scan_MF_UR$`Male unemployment rate`)
hist(sqrt_male_unemployment_rate)
```



```
#Female unemployment rate before transformation.
hist(scan_MF_UR$`Female unemployment rate`)
```

```
#Female unemployment rate after transformation.
sqrt_female_unemployment_rate <- sqrt(scan_MF_UR$`Female unemployment rate`)
hist(sqrt_female_unemployment_rate)
```



Purpose of transformation: The purpose of this transformation is to decrease the skewness of the dataset and transform the distribution into a normal distribution.

Step explaination:

- Firstly, I applied transformation to the male unemployment rate dataset using the sqrt() function.
- Secondly, I applied transformation to the female unemployment rate dataset using sqrt() function.

Decision: After trying five different data transformation (log10, log, squared, sqrt, and BoxCox), I found that square roots are the transformation that is closest to the normal distribution for variable male unemployment rate and female unemployment rate. Therefore, sqrt() function will be the one choosen/used for this transformation.

note: I couldn’t put the other 4 histogram (log10, log, squared, and BoxCox) due to page limit (25 pages).
